

## CONCEPTS

**SELinux = LABELING** system

Every process, file, directory, system object has a LABEL.

Policy rules control access between labeled processes and labeled objects.

The kernel enforces these rules.

**Labeling** → files, process, ports, etc. (system objects)**Type enforcement** → Isolates processes from each other based on types

## LABELING

Label format:

user:role:type:level (optional)

user → identity known to the policy authorized for a specific set of roles and a specific MLS/MCS range

role → attribute of RBAC, serves as an intermediary between domains and SELinux users

type → attribute of type enforcement, defines a domain for processes and a type for files

level → attribute of MLS/MCS, pair of levels, written as lowlevel-highlevel if the levels differ, or lowlevel if the levels are identical

## TYPE ENFORCEMENT

Targeted: Processes that are targeted run in a confined domain, and processes that are not targeted run in an unconfined domain

Multi-level security (mls): Control processes (domains) based on the level of the data they will be using

Multi-category security (mcs): Protects like processes from each other (like VMs, OpenShift Gears, SELinux sandboxes, containers, etc.)

## SELINUX MODES @ BOOT

Kernel parameters:

**enforcing=0** → boot in permissive mode**selinux=0** → kernel to not load any part of the SELinux infrastructure**autorelabel=1** → forces the system to relabel

If you need to relabel the entire system:

# touch /.autorelabel

# reboot

If the system labeling contains a large amount of errors, you might need to boot in permissive mode for the autorelabel to succeed.

## SELINUX STATES

## CHECK STATUS:

**enforcing** SELinux security policy is enforced**permissive** SELinux prints warnings instead of enforcing**disabled** No SELinux policy is loaded

Configuration file:

**/etc/selinux/config**

Check if SELinux is enabled:

SELinux status tool:

Enable/disable SELinux (temporarily):

# **getenforce**# **sestatus**# **setenforce [1|0]**

EXAMPLE OF LABELING: APACHE WEB SERVER			CHECK/CREATE/MODIFY SELINUX CONTEXTS/LABELS:
Binary	<code>/usr/sbin/httpd</code>	<code>httpd_exec_t</code>	Many commands accept the argument <code>-Z</code> to view, create, and modify context: <code>- ls -Z</code> <code>- id -Z</code> <code>- ps -Z</code> <code>- netstat -Z</code> <code>- cp -Z</code> <code>- mkdir -Z</code> Contexts are set when files are created based on their parent directory's context (with a few exceptions). RPMs can set contexts as part of installation.
Configuration directory	<code>/etc/httpd</code>	<code>httpd_config_t</code>	
Logfile directory	<code>/var/log/httpd</code>	<code>httpd_log_t</code>	
Content directory	<code>/var/www/html</code>	<code>httpd_sys_content_t</code>	
Startup script	<code>/usr/lib/systemd/system/httpd.service</code>	<code>httpd_unit_file_d</code>	
Process running	<code>/usr/sbin/httpd -DFOREGROUND</code>	<code>httpd_t</code>	
Ports (netstat -tulpnZ)	80/tcp, 443/tcp	<code>httpd_t</code>	
Port type (semanage port -l)	80, 81, 443, 488, 8008, 8009, 8443, 9000	<code>http_port_t</code>	
TROUBLESHOOTING			
SELinux tools:	<code># yum -y install setroubleshoot setroubleshoot-server</code>		← Reboot or restart auditd after you install
Logging:	<code>/var/log/messages</code>	<code>/var/log/audit/audit.log</code>	<code>/var/lib/setroubleshoot/setroubleshoot_database.xml</code>
<b>journalctl</b>	List all logs related to setroubleshoot:	<code># journalctl -t setroubleshoot --since=14:20</code>	
	List all logs related to a particular SELinux label:	<code># journalctl _SELINUX_CONTEXT=system_u:system_r:policykit_t:s0</code>	
<b>ausearch</b>	Look for SELinux errors in the audit log:	<code># ausearch -m AVC,USER_AVC,SELINUX_ERR -ts today -i</code>	
	Search for SELinux AVC messages for a particular service:	<code># ausearch -m avc -c httpd -i</code>	
Edit/modify labels (semanage)	know the label:	<code># semanage fcontext -a -t httpd_sys_content_t '/srv/myweb(/.*)?'</code>	
	know the file with the equivalent labeling:	<code># semanage fcontext -a -e /srv/myweb /var/www</code>	
	Restore the context (for both cases):	<code># restorecon -vR /srv/myweb</code>	
Edit/modify labels (chcon)	know the label:	<code># chcon -t httpd_system_content_t /var/www/html/index.html</code>	Note: If you move instead of copy a file, the file keeps its original context.
	know the file with the equivalent labeling:	<code># chcon --reference /var/www/html/ /var/www/html/index.html</code>	
	Restore the context (for both cases):	<code># restorecon -vR /var/www/html/index.html</code>	
Add new port to service:	<code># semanage port -a -t http_port_t -p tcp 8585</code>		← SELinux needs to know
<b>Booleans</b>	Booleans allow parts of SELinux policy to be changed at runtime without any knowledge of SELinux policy writing.		
To see all booleans:	<code># getsebool -a</code>	To see the description of each one:	<code># semanage boolean -l</code>
To set a boolean execute:	<code># setsebool [boolean] [1 0]</code>	To configure it permanently, add -P:	Example : <code># setsebool httpd_enable_ftp_server 1 -P</code>
